Determinants of Domestic Investment in Jordan: ARDL Techniques

Suleiman W. Almasaied*

ABSTRACT

The study investigates the determinants of domestic investment in Jordan with time series data during the 1980-2005 period with focus on post-reform era efforts. Both the short-run and long-run movement of the investment process are modelled using the recent developed autoregressive distributed lag (ARDL) approach to cointegration. The results are confirming previous results found in empirical literature. Namely, the growth rate of GDP and exports are significant in stimulating domestic investment. Foreign Direct Investment (FDI) “crowds in” domestic investment but with less magnitude. In addition, the development level of financial sector and human capital is crucial for stimulating domestic investment only in long term. While, increase in domestic credit availability enhancing domestic investment in short-run. Hence, it is arguably worthy for the authorities to go on post-reform era efforts by encouraging both exports expansion, sustain current GDP growth rates and attracting more FDI to stimulating domestic investment.

Keywords: Investment, FDI, Financial Intermediation, ARDL, Jordan

1. INTRODUCTION

There are theoretically and empirically consensus on the relation between domestic investment and economic growth, but, there isn't a same consensus on FDI and economic growth. Thus, the focus and the attention of both researchers and policy-makers were on FDI inward to find empirical evidence on FDI-lead growth hypothesis. Recently, empirical evidence suggests that the fastest growing countries are the biggest FDI-host countries (Fabry and Zeghni, 2002), which, lead to more attention on the determinants of FDI than domestic investment. However, after Asian financial crisis, the attention was back to domestic factors such as domestic investment as a leader of economic growth. How domestic investment increased in some developing countries and in others did not? In particular, what causes domestic investment and what retards it? These questions were been asked.

Jordan records good rates of economic growth during the first half of 2000s as it ranged from 4.1% to 7.7%, but in contrast, domestic investment growth rates did not show any improvement during 2000s. therefore, it is important to discuss this matter, especially it is well known that high domestic investment growth rates are critical in generating economic growth especially in countries such as Jordan that are characterized by scarcity of recourses, high unemployment and poverty rates. Therefore, policy-makers need to know what factors those are crucial in determining the long-run domestic investment process. In particular, what causes domestic investment in Jordan and what retards it? and is FDI contributing directly to domestic investment stimulation?

The purpose of this paper are: first to investigate the long and short-run determinants of domestic investment in Jordan as one of the emerging economies; that seeking to encourage domestic investment as well as enhancing foreign investment and hereafter increase its economic growth. Second, to examine empirically the role of FDI on domestic investment, namely, whether, there is evidence that the inflow of FDI "crowded in" domestic investment or not.

This paper contributes to the literature in the following ways: first, a large body of the literature on the inflows of foreign direct investment and emphasized how to encourage it as it has a vital role in economic growth, but there is shortage of empirical literature on the domestic investment and its determinants, as most of literature show that both domestic and foreign investment lead to high growth rate. Second, many empirical studies

* Faculty of Financial and Business Administration, Al al-Bayt University, AlMafraq, Jordan. Received on 16/12/2006 and Accepted for Publication on 7/10/2007.
have been carried out on the relationship between domestic investment in developing countries and its determinants, the results are mixed. The ambiguous results of existing studies, mainly stemming from the inappropriate econometric methods, call for further study of methodology and empirical model building. The results from the autoregressive distributed lag (ARDL) approaches due to Pesaran et al. (2001) are more likely to be more persuasive than their predecessors. The use of the ARDL test is necessary because the power of conventional unit root tests may be low for a time span typically available for empirical works. The approach also allows us to take on the estimation problem of data nonstationarity and differentiate between long and short-run relationships.

Finally, this research was conducted following recent economic reform efforts in Jordan of adoption of laws that encourage both domestic and foreign investment. that result in increase in economic growth rates in during the 2000s combined with of the inflow of foreign capital, new technology, export expansion, and the search for new policy options that could contribute to accelerate domestic investment in Jordan.

The policy concern of this finding in post-reform era is clear: if it is positive both in the short and long-run as shown by our results that development of domestic factors as well as external capital may lead to domestic investment acceleration. Thus, it is important for Jordan to restructure and develop domestic factors (such as financial intermediation, human capital, exports) structure for undertaking efficient investment allocation and to cater for an external capital market that is showing greater interest in Jordan's emerging economy.

The remainder of the paper is organized as follows. Section 2 reviews Jordan’s economic background. This is followed by the relevant theoretical and empirical consideration. Sections 4 provide econometric method. Section 5 contains data description and empirical results. Finally, the last section contains the concluding remarks.

2. JORDAN’S ECONOMIC BACKGROUND

By the end of 1990s, Jordan has a conducive corporate environment, in terms of modernising the bureaucracy of the state, tariffs, taxes, employment constraints, adapting the financial and educational systems in view the new challenges brought by globalization and the modernization of infrastructures, particularly in the fields of transport and telecommunications, profit repatriation and the protection of property rights.

Jordan became an attractive channel for duty and quota-free access to major world markets, including the European Union (EU) and the United States (US) after establishing of Qualified Industrial Zones (QIZ) in 1997 (Ministry of Industry and Trade, 1997, 2000), that are industrial parks from which goods can be exported duty free to the United States and entered the World Trade Organization (WTO) in 2000, signed a free trade agreement with the US in the same year, prior to concluding an association agreement with the EU in 1999 (Ministry of Industry and Trade, 1999). Furthermore, Jordan mad efforts to adoption of laws that encourage FDI which is a vehicle for new technology.

The empirical evidence that suggest with "high-tech" and low wages, production of high-tech products in the low-wage country yields an extra-profit or a rising market share for domestic producers or foreign investors. This extra-rent may be an important source of catching up of developing countries, and Jordan as well as the other developing countries seeking for this issue.

The Jordan's economy has, in fact, shown inconsistent growth rates. Table (1) shows that Jordan had rapid GDP growth rates during the 1980s, while it had the lowest growth rates during 1990s (around 2 %), and good rates during the first half of 2000s as it ranged from 4.1% to 7.7%, but in contrast, domestic investment ratio did not show any improvement during 2000s. With exception of 1980s, domestic investment as a percentage of GDP was a modest percentage and it ranged between 19% and 22% during the 1990s and first half of 2000s. The gross domestic investment was matched mostly by low rates of domestic savings as shown in the table. Thus, the need arises to fill the gap in resource by the inflow of foreign capital, mainly in the form of either Foreign Direct Investment (FDI) or foreign borrowing.

Over the years financial deepening as measured by M2/GDP in Jordan took place. For instance, the ratio increased from 85 % in 1980 to 113 % in 1990 and from 124 % in 2000 to 133 % in 2004. Indeed, various policies and measures have been introduced to promote exports of goods. Therefore, Jordan integration efforts led to a significant increase in new FDI as well domestic investment. For example, there is a surge in FDI into Jordan's Qualifying Industrial Zones (QIZs) motivated by the country's privileged access to the United States.
market for goods produced in those qualifying zones. The total amount of investments in Jordan's QIZs has reached (600$) million, and the total exports jumped from (700) million JD in 1990 to more than (2700) million JD in 2004, around (30%) of the total exports is going to United States of America market (Almasaied, 2006).

3. THEORETICAL AND EMPIRICAL CONSIDERATION

A number of models have been employed in the literature to explain the determinants of investment, among these models: Neoclassical investment model and accelerator investment model. Neoclassical model has been criticized for its shortcomings in estimating investment function for developing countries. These criticisms are related to the lack of readily available measures of capital stock and/or returns to capital (Blejer and Khan, 1984). In that regard, the study will consider accelerator investment model for the same reason.

Fry (1998) established a flexible accelerator model and developed by Agrawal (2000). Fry developed investment model in terms of the ratio of investment to GDP based on the flexible accelerator model. The accelerator model has desired capital stock $k^*$ proportion to real output, $y$:

$$k^* = \alpha y$$  \hspace{1cm} (1)

This can be expressed in terms of desired ratio of net investment to output $(I/Y)^*$:

$$(I/Y)^* = \alpha \gamma$$  \hspace{1cm} (2)

Where $I$ is gross domestic investment in current prices, $Y$ denotes GDP in current prices and $\gamma$ is the growth rate of real GDP. A partial adjustment mechanism allows the actual investment rate to adjust to the difference between the desired investment rate and the investment rate in previous period:

$$\Delta(I/Y) = \lambda [(I/Y)^* - (I/Y)_{t-1}]$$

or

$$I/Y = \lambda (I/Y)^* + (1 - \lambda)(I/Y)_{t-1}$$  \hspace{1cm} (3)

Where $\lambda$ denotes the coefficient of adjustment. The flexible accelerator model allows economic conditions to influence the adjustment coefficient $\lambda$. Specifically:

$$\lambda = \beta_0 + \left[ \beta_1 Z_1 + \beta_2 Z_2 + \beta_3 Z_3 + \ldots \right] \left( (I/y)^* - (I/Y)_{t-1} \right)$$  \hspace{1cm} (4)

Where $Z_i$ are the variables (include an intercept term for constant depreciation rate) that affect $\lambda$ rate, and $\beta_i$ are their respective coefficients.

Ghura and Goodwin (2000) also employed the following empirical framework to analysis of the determinants of domestic investment using panel data from (31) developing countries:

$$y_i = \alpha + \beta X_i + e_i$$  \hspace{1cm} (5)
Where \( y_i \) is the ratio of domestic investment to GDP, \( X_i \) are the observable variables representing factors affecting domestic investment, \( \alpha \) and \( \beta \) are parameters to be estimated, and \( \varepsilon_i \) is a random error term with a mean of zero.

In this line of research, most researchers have included all or a subset of the following variables (among others) as the exogenous variables in the domestic investment equation: FDI, financial intermediation, exports, human capital, and domestic credit availability. See for example: Ghura and Goodwin (2000), Fry (1998), and Agrawal (2000). These studies implicitly assumed the existence of an underlying equilibrium relationship between domestic investment and a given set of explanatory variables. Our estimation technique differs from these earlier studies in the way that handles the nonstationarity feature of the data. Theoretically, most literature pointed out that all these variables contribute positively to the growth of domestic investment in developing countries (see among others: Lucus, 1998; Romer, 1990; Borensztein, et al., 1998; Levin and Beck, 2000; Gura and Goodwin, 2000; Madsen, 2002). Specifically, the model used is:

\[
GDI = \beta_0 + \beta_1 Gr + \beta_2 FDI + \beta_3 FI + \beta_4 H + \beta_5 Cr + \beta_6 X + t + \varepsilon
\]  
(6)

Where:
- GDI Denotes domestic investment (net of FDI),
- Gr Denotes the growth rate of real GDP,
- FDI Denotes foreign direct investment as a ratio of GDP,
- X Denotes the exports of goods and services as a ratio of GDP,
- FI Denotes financial intermediation as calculated by M2 as a ratio of GDP,
- H Denotes human capital proxied by secondary school enrolment ratio,
- Cr Denotes domestic credit availability as a ratio of GDP,
- T Denotes trend,
- \( \varepsilon \) Denotes error term

4. ECONOMETRIC METHOD

We apply the ARDL approach proposed by Pesaran et al. (2001) to estimate equation 6. The following ARDL model is estimated to examine the long-run relationship:

\[
\Delta GDI = \alpha_0 + \alpha_1 Gr_{t-1} + \alpha_2 H_{t-1} + \alpha_3 X_{t-1} + \alpha_4 GDI_{t-1} + \alpha_5 FI_{t-1} + \alpha_6 DFI_{t-1} + \alpha_7 Cr_{t-1} + \beta_1 \sum_{i=1}^{n} FDI_{t-i} + \beta_2 \sum_{i=1}^{n} \Delta Gr_{t-i} + \beta_3 \sum_{i=1}^{n} \Delta H_{t-i} + \beta_4 \sum_{i=1}^{n} \Delta X_{t-i} + \beta_5 \sum_{i=1}^{n} \Delta FDI_{t-i} + \beta_6 \sum_{i=1}^{n} \Delta Cr_{t-i} + B_4 t
\]  
(7)

The choice of the correct lag is a crucial issue in these tests. There are many information criteria such as Akaike Information Criteria (AIC), Schwarz Bayesian Criteria (SBC) and Log-likelihood Ratio (LR) statistic that can be used to select the optimal lag length. In this study, we rely on SBC, because it chooses the most parsimonious model, consistent, have small sample properties and performs slightly better in the majority of their experiments (see Morimune and Mantani, 1995; Quinn, 1988; Pesaran and Shin, 1999; Alam and Quazi, 2003; Almasaied, 2006, 2007). It is worth noting that the sample size in this study was limited to 35 observations, and with 6 variables. Thus, the maximum order of appropriate lag structure for a VAR model was set to 3 to address this limitation. The results based on SBC criteria suggest that the optimal lag is one.

One of the important advantages of ARDL procedure was that the estimation is possible even when the explanatory variables are endogenous (Alam and Quazi, 2003). Furthermore, as long as the ARDL model is free of residual correlation, endogeneity is less of a problem. Pesaran and Shin (1999) showed that the appropriate lags in the ARDL model are corrected for both residual correlation and endogeneity. The important advantage of ARDL against the single equation cointegration analysis such as Engle and Granger (1987) is that Engle and Granger suffer from problems of endogeneity while the ARDL method can distinguish between dependent and explanatory variables. According to Pesaran and Pesaran (1999), the ARDL method has additional advantage of yielding consistent estimates of the long-run parameters that are asymptotically normal irrespective of whether the variables are I(0), I(1) or mutually integrated.

Furthermore, the ARDL method estimates the long and short-run components of the model simultaneously,
removing problems associated with omitted variables and autocorrelation. Thus, estimates obtained from the ARDL method of cointegration analysis are unbiased and efficient, since they avoid the problems that may arise in the presence of serial correlation and endogeneity (Siddiki, 2000; Siddiki, 2002, Almasaied, 2007).

5. DATA AND EMPIRICAL RESULTS

5.1 Sources of Data
The annual data for Jordan was computed from different sources and the time period spanning is 1980 to 2005. The data definitions and statistical sources used in this study are listed in Table (2).

5.2 Long-Run Equilibrium Estimation
To explore the existence of long run relationship or cointegration among the variables in the model (7), we employed ARDL test proposed by Pesaran et al., (2001). The existence of a unique long-run relationship is crucial for valid estimation and inference about the parameters of the models. One of the important advantages of ARDL procedure was that the estimation is possible even when the explanatory variables are endogenous (Alam and Quazi, 2003). Furthermore, as long as the ARDL model is free of residual correlation, endogeneity is less of a problem. Pesaran and Shin (1999) showed that the appropriate lags in the ARDL model are corrected for both residual correlation and endogeneity.

The Schwarz Bayesian Criteria (SBC) selects an ARDL (1,0,0,1,0,0) domestic investment models for Jordan. The results of ARDL model of Jordan's domestic investment are reported in Table (3). As can be seen from the table, most of the variables are significant and the signs are consistent with a priori expectation. With exception of credit availability, real GDP growth, FDI, financial intermediation and exports statistically have significant positive effect on domestic investment. The long-run results of ARDL for Jordan data indicate that the expansion of exports of goods and services is a key determinant of domestic investment. The coefficient of exports indicated that exports had a larger impact on domestic investment, which suggest that a 1 million JD increase in the exports could result in 62 million JD increase in domestic investment accumulation. Our result confirms similar results of Jansen, 1995, and Cuvers (1996) for groups of developing countries. In addition, the estimation results provided support for a complementarily between domestic investment and foreign direct investment (FDI) that means FDI has a strong stimulus effect on domestic investment. This suggests that a 1 million JD increase in FDI could result in an increase in domestic investment by 17 million JD, which indicated the inflow of FDI “crowds in” domestic investment in Jordan, and confirming a similar finding of Borensztein, et al., (1998).

The long-run estimation indicates that improvement of financial intermediation (captured by ratio of borrowed money to GDP) is boosting domestic investment by their contribution to lowering the requirement to finance and thereafter lowering the cost of borrowing. This result is in line with the hypothesis that financial intermediaries provide the link between the financial and the real sector and confirmed theoretical literature arising out of the McKinnon and Shaw hypothesis (McKinnon 1973, Shaw 1973) and confirmed the findings of Fry (1998); Ghura and Goodwin (2000), and Agrawal (2000).

As shown from the table, the real growth of real GDP is an important determinant of domestic investment, confirming the results of Greene and Villanueva (1991) and Ghura and Goodwin (2000), and it is consistent with the findings of Blomstrom et al. (1996) where there is a causality from economic growth to gross investment and confirmed the result of Madsen, (2002) regarding policies that seek to enhance investment which are effective means of promoting economic growth. Booth (1999) argued that rapid growth lead to high rates of investment and vice versa. See also: De Long and Summers, (1992); Chaudhari and Wilson, (2000); Podrecca and Carmeci, (2001), and Krishnna et al., (2003).

Another interesting result arising from long-run ARDL result relates to the important role of educational development in Jordan in stimulating domestic investment which is consistent with theories saying that the higher the educational development (as proxy for the human capital ) the higher the level of domestic investment (see: Borenszttein et al., 1998 and Ghura and Goodwin, 2000). While the increase in domestic credit did not appear to have a significant impact on domestic investment in the long-run, but it had a significant impact in short-run as will be seen in ECM result in the next section.

5.3 The ECM Estimation
The short-run dynamics of domestic investment function in Jordan was also estimated using the ARDL
approach to cointegration of Pesaran et al. (2001). The results of ECM estimation based on the ARDL technique for domestic investment model along with diagnostic tests are reported in Table (4).

The diagnostic statistics in Table (4) indicated that the equation was well specified. None of the statistics shown in the table were significant at the 5% significance level. The model fulfilled the conditions of non-autocorrelated, homoskedasticity and normal distribution; i.e. the $\chi^2$ tests showed no evidence on residual serial correlation, while the Ramsey’s RESET tests showed no functional form of misspecification. Furthermore, the $\chi^2$ tests did not indicate any evidence of normality problem or heteroscedasticity of residual. Indeed the Adjusted $R^2$ is 0.836 suggesting that the Error Correction Models (ECM) fitted the data reasonably well.

The period [No. of Obs.] 1980-2005 [36]

Note: Following Pesaran et al. (2001), lag order of the ARDL model was selected using Schwarz Bayesian Criteria (SBC) and the LM tests for testing residual correlation. Asterisks ***, **, * represent 1%, 5%, 10% significant levels, respectively. The t-ratios are reported in square brackets. The following notation applies: Gr, denotes growth rate of gross domestic product; GDI, gross domestic investment; FDI, foreign direct investment; FI, financial intermediation (M2/GDP); H: human capital; X: exports of goods and services. T: not significant thus omitted from the table.

As shown in Table (4), the estimated values of the lagged error-correction term ($ECM_{-1}$) based on ARDL method is -0.5702 and statistically significant, which suggest that the ECM tends to cause domestic investment to converge monotonically to its long-run equilibrium path in relation to changes in the exogenous “forcing variables”. Again the statistically significant and the correct sign of $ECM_{-1}$ coefficients confirm the presence of long-run equilibrium between domestic investment and its determinants.

The empirical results also showed that the short-run movement in most of the variables of domestic investment equation had the correct signs and were statistically significant, suggesting the existence of long-
term relationship between the model’s variables. The coefficients of exports (0.3517) and growth rate of GDP (0.255) carry positive signs and are noticeably larger than most of the other variables in ECM. This result indicates that if the growth rates of both real GDP and export will be sustainable during the next years as in the period 2000-2005, the growth rates of domestic investment will be better than during pre 2000s period. Since the growth rate of both GDP and exports were very small during the 1980s and 1990s decades compared to 2000s, this could be the reason why growth rate of domestic investment in Jordan was weak and ultimately to slow the economic growth during the pre-2000s period.

The empirical results suggest that the inflow of FDI have a “crowd in” effect on domestic investment, and there was complementary relationship between FDI and domestic investment in Jordan. Another important point is that FDI had a smaller impact on domestic investment stimulation. For example, this results suggest that 1 million JD increase in FDI inflow to Jordan could result in an increase in domestic investment by only 90 thousand JD. Also, the results showed that the availability of domestic credit had a short-run effect on domestic investment while financial intermediation and human capital showed no clear effect on domestic investment in the short-term.

These results are consistent with the previous findings in that the growth of real GDP stimulates domestic investment (see: De Long and Summers, 1992; Chaudhari and Wilson, 2000; Ghura and Goodwin, 2000; Podrecca and Carmeci, 2001). Booth (1999) argued that rapid growth leads to high rates of investment and vice versa. Numerous studies including Carkovic and Levine (2002), Marchant, et. al., (2002), Agrawal (2000) and Graham and Krugman (1991) found that the increase in the FDI inflows were associated with a many-fold increase in investment by national investors. For example, Borensztein et. al. (1998) investigated the effect of FDI on domestic investment. His results were supportive of “a crowding in” effect, and he found that a 1 US$ increase in the net inflow of FDI is associated with an increase in total investment in the host economy by more than 1 US$. Borensztein interpreted his finding by the advanced technology and advanced management skills carried by FDI transfer to domestic investment. Our study confirmed that the expansion of the export of goods and services inspired domestic investment (see: Jansen, 1995; Cuvers, 1996).

Finally, we examined the stability of the long run parameters together with the short-run movements for each equation. To this end, we relied on the CUSUM and CUSUMSQ tests proposed by Brown et. al. (1975). The same procedure has been applied by Pesaran and Pesaran (1997) and Bahmani-Oskooee et. al. (2002) to test the stability of the long-run coefficients. The tests applied to the residuals of the ECM models (Table 4). As can be seen from Figure (1), the plots of CUSUM and CUSUMSQ statistics stayed within the critical 5% bounds for all equations. Neither CUSUM nor CUSUMSQ plots crossed the critical bounds, indicating no evidence of any significant structural instability. These results were the same no matter which selection criterion was chosen, which indicated that the domestic investment function in Jordan is stable. Again it appears to be unaffected by the 1989 crisis over the sample period.

Note: Following Pesaran and Shin (1997), lag order of the ARDL model was selected using Schwarz Bayesian Criteria (SBC) and the LM tests for testing residual correlation. Asterisks ***, **, * represent 1%, 5%, 10% significant levels, respectively. The $t$-ratios are reported in square brackets. The following notation applies: Gr, denotes growth rate of real gross domestic product; GDI, gross domestic investment; FDI, foreign direct investment; FI, financial intermediation (M2/GDP); H: human capital; X: exports of goods and services. The probabilities of $\chi^2$ for the diagnostic tests are represented in square brackets. A: Lagrange multiplier based on the Breusch-Pagan LM test for residual serial correlation; B: Ramsey's RESET test using the square of the fitted values; C: Based on a test of skewness and kurtosis of residuals; D: Based on the regression of squared residuals on squared fitted values. $T$: was not significant thus omitted from the table.

Figure 1. Plots of CUSUM and CUSUMSQ Statistics for Jordan’s Domestic Investment Model

6. CONCLUSION

The determinants of domestic investment in Jordan as well as in developing countries have been widely investigated by a number of studies but the results are ambiguous. This study has extended the investigation using appropriate and recent econometric methods that is Autoregressive Distributed Lag (ARDL) approaches according to Pesaran et al. (2001). The results from ARDL are more likely to be more persuasive than their predecessors. Indeed, it contributes to literature by using recent data to cover post economic reform period in Jordan that results in adoption of new laws to encourage both domestic and foreign investment which resulted in increasing economic growth rates during the first half of 2000.

Domestic investment in Jordan is stimulated by real GDP growth as well as expansion of exports of goods and services. This result indicating that if the growth rates of both real GDP and exports will be sustainable during the next years as in the period 2000-2005, the growth rates of domestic investment will be better than during pre 2000s period. Also, FDI inflows to Jordan is “crowd in” domestic investment but with less magnitudes than GDP growth and exports expansion. In addition, the development level of financial sector and human capital is crucial for stimulating domestic investment in long term. Whereas, the increase in domestic credit availability will enhance domestic investment in the short-run. Hence, it is arguably worthy for the authorities to encourage both export expansion and FDI inflows to stimulate domestic investment and thereafter economic growth.
